Abstract

This document provides a statistical estimation of checkpoint passage times based on a given total race time. These calculations are intended to help runners plan their race strategy. Additionally, we include information about sun and moon positions to assist with overall race planning and strategy, and weather data obtained from `open-meteo.com`.

THIS IS A WORK IN PROGRESS

Source code: `github.com/thanasisn/ROUT_analysis`

Data

All performance data were obtained directly from the race website (www.rout.gr). The location of each checkpoint along the race route was derived from the race GPX track and associated maps. The astronomical data were computed with `astropy` and `ephem` Python modules, and the meteorological data were obtained through `open-meteo.com` API for each check point, at the time of this document creation.

Classes of performance models from the 2025 race results

Based on the distribution of total finishing times, we assume there are 5 distinct classes of athletes. To construct a corresponding number of models, finishing times were partitioned into equal-sized bins. At this stage, no additional athlete characteristics (such as age, gender, or experience) are considered. For any given total time, the class corresponding to its bin is used.

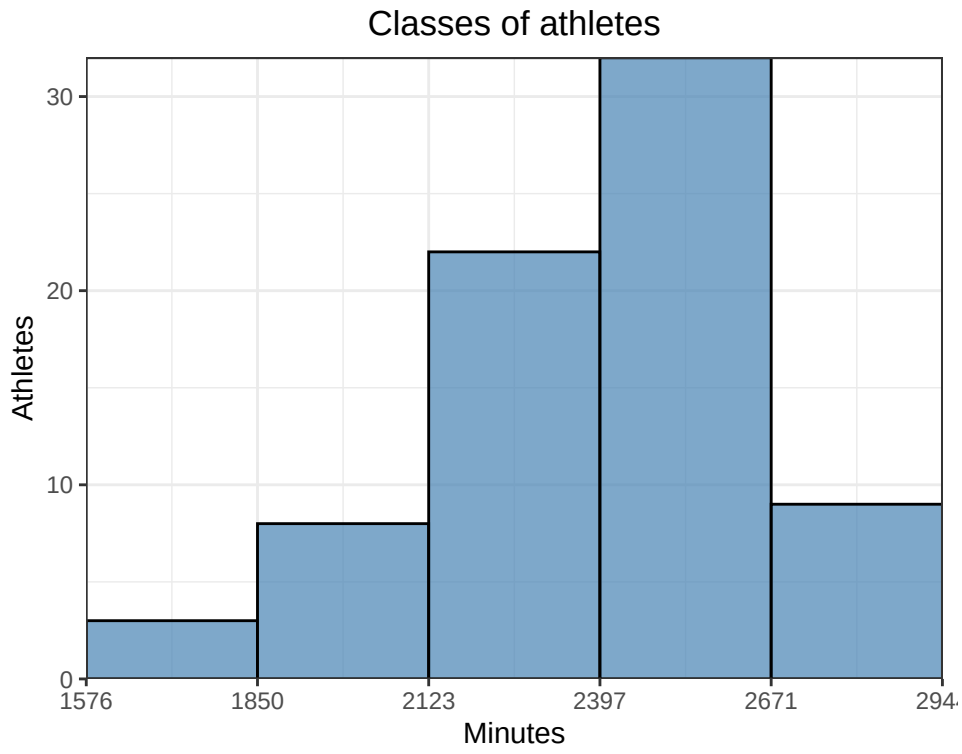

Figure 1: Distribution of finishing time in minutes for the 5 classes

For each class and for each segment between consecutive checkpoints, we calculated the corresponding mean pace (minutes per kilometer) and mean speed (kilometers per hour), along with other statical measures. For each class, these values will be scaled to obtain the corresponding passes from each CP. We also computed the average pace and speed from the start of the race to each checkpoint. The actual source code is displayed below.

```
models <- data.table()
for (id in unique(DT$binid)) {
    tmp <- DT[binid == id]
    tmp <- remove_empty(tmp, "cols")

            across(
                contains("K-"),
                list(
                  mean = ~mean(.x, na.rm = TRUE),
                  median = ~median(.x, na.rm = TRUE),
                  min = ~min(.x, na.rm = TRUE),
                  max = ~max(.x, na.rm = TRUE),
                  sd = ~sd(.x, na.rm = TRUE),

The detailed model parameters are shown in Table 1. A comparison of the classes can be seen in the Figure 2 based on elapsed time, and on Figure 3 based on covered distance.

Create prediction for each hour within it's class

Predict passes for a range of finishing time. This was posted on-line. Sun angles are computed at the actual location of each check point.

Evaluate models against 2026 results.

For all finishers estimate pass times from each CP, using the appropriate class model. Prediction are based on individual finishing time.

We excluded finishing time from the statistical evaluation, as the modelled finishing time is equal.

Departures by CP

We calculated the departure in per cent of each athlete actual CP pass time from the estimated, based the class he belongs based on actual finishing time.

Departures by athlete

We tested the actual passes of each athlete by prediction based on its finishing time. We computed the deviation of actual pass time from the predicted (Actual pass time minus predicted passes). So positive values indicate that the actual time is longer than expected, and thus the athlete slower than expected, from the prediction. The blue line is the cumulative time differences along all prediction. While the blue line move upwards the athlete is slower than expected as the positive time is explained by taking more time than the prediction.
